

BRAINWAVE 2026 · BLOCKCHAIN TRACK · RESUBMISSION

AgentifyOS

The marketplace where AI agents shop for tools. A developer lists a paid API in 60 seconds. An agent finds it mid-task, pays a fraction of a cent, and gets on with the job. No signup, no API key, no human in the loop.

LIVE ON ALGORAND TESTNET

6 SETTLEMENTS, REAL USDC

14 LISTINGS

X402 · GOPLAUSIBLE FACILITATOR

An AI agent can reason, but it cannot buy.

Every API an agent might want sits behind a signup form, a credit card and a dashboard, all of it built for a human with a company card. So agents work on a leash: a person guesses in advance which tools the agent will need, provisions keys, and hopes.

FOR THE BUYER

The leash

An agent that discovers a useful API mid-task cannot use it. It has no account, and no way to open one.

FOR THE SELLER

The floor

Billing makes anything under a dollar not worth selling. So nobody sells the \$0.002 call, however useful it is.

FOR BOTH

The mismatch

Agents want thousands of tiny calls across many vendors. Subscriptions want one big commitment to one.

This is not a technology gap. Payments work fine. It is a **market gap**: there is nowhere a machine can shop.

Two customers, one missing marketplace.

SUPPLY SIDE

The developer with an API

- TODAY** Has something worth \$0.005 a call. Building signup, billing, quotas and invoicing to sell it costs more than it would ever earn, so it never ships.
- WITH US** Fills in a manifest, sets a price, publishes. Gets paid per call in USDC, settled on-chain, with no account system to build or run.
- 14 listings in the catalog today, from 6 publishers, priced \$0.002 to \$0.020.

DEMAND SIDE

The agent builder

- TODAY** Pre-provisions every key the agent might need, hands it credentials it should not hold, and pays monthly for tools it used twice.
- WITH US** Gives the agent a wallet and a budget. It discovers tools at runtime, pays for exactly what it uses, and stops when the budget runs out.
- Works today from a terminal, from an MCP client like Claude or Cursor, or over plain HTTP.

The same listing serves both

01

More listings

Publishing costs a manifest and a price, so the catalog grows cheaply.

02

More agents shop

Agents go where there is something to buy, and there is nowhere else yet.

03

More settled calls

Every call is a payment on-chain, and a fifth of it is our revenue.

04

Better reputation

Settled payments rank the catalog, which makes it worth listing on.

A marketplace, not a payment demo.

SURFACE	WHO USES IT	WHAT IT DOES
Catalog	developers, buyers	Browse and search 14 listings by category, price ceiling and tag. Every listing carries its schema, example output and price.
Publish	developers	A manifest, a price, a payout address. The listing is live and machine-discoverable immediately.
Agent demo	everyone	Type a task in plain English. Watch an agent plan it, buy the tools it needs, and show every payment on the wire.
Dashboard	developers	Earnings per listing, settled calls, and the reputation those payments produced.
CLI and MCP	agent builders	<code>agentify call <slug></code> , or wire the MCP server into Claude or Cursor and let the assistant buy tools itself.
Discovery API	agents	The whole catalog as machine-readable records, plus <code>llms.txt</code> , so an agent can shop without a browser.

Reputation is the payment. There are no reviews to game: a listing's standing is derived from calls that actually settled on-chain, and faking that costs real money.

Five steps, none of which involve a human.

What the buyer needs

A wallet with USDC, and a budget. That is the whole onboarding: no account, no key, no card, and no ALGO, because the facilitator pays the network fee.

What the seller needs

An address that can receive USDC. Payment lands directly and we never custody it. The seller runs no facilitator and holds no key of ours.

The rails got standardised. Nobody opened the shops.

FIRST

Agents became buyers

Tool use went from a demo to the default. Agents now run long tasks needing data they were never provisioned for.

THEN

x402 standardised payment

HTTP 402 finally means something. A machine can be quoted a price and pay it inside the same request.

THE GAP

Almost nothing is for sale

The protocol defines how to pay. It does not create anything to buy. The supply side is where the market is.

Payment rails without merchants are just plumbing. **We are building the merchants, and the place they sell.**

The gap, in the facilitator's own numbers

SETTLEMENTS / 24H 12,601 x402 payments already clearing	MERCHANTS 127 everyone selling, worldwide	ON ALGORAND 99% 12,511 of 12,524 listed resources	FACILITATORS 1 GoPlausible, the one we settle through
--	--	--	--

From facilitator.goplausible.xyz/discovery/all, 17 Aug 2026. Twelve thousand payments a day against 127 sellers is not a demand problem. **It is a supply problem, almost entirely on Algorand.**

One sentence in. Four paid tools out. Four cents.

What a user types

```
"Get the live ALGO price, scrape
algorand.co/blog, summarize it,
and attest the summary."
```

```
budget: $0.10
```

It stops the moment the budget cannot cover the next call. That is the point: **the budget is the leash, not a person.**

What actually happened

```
run ok: true   spent $0.037   left $0.063
```

```
four settlements on Algorand testnet,
each one a real USDC transfer
```

Live at agentifyos.xyz/agent, with the full wire trace.

The same purchase, from three places, none of them privileged

IN THE BROWSER

The agent demo

Type a task, watch it buy. No wallet needed: a shared testnet account under a daily cap.

IN A TERMINAL

The CLI

```
agentify call <slug> . Its own key and
budget, over the same public endpoint.
```

IN AN ASSISTANT

The MCP server

Wire into Claude or Cursor and the assistant buys tools itself, under a spend cap you set.

Real money moved, and you do not have to trust us.

SETTLEMENTS	VALUE MOVED	BUYER'S FEE	BUYER'S ALGO
6 17 Aug 2026, Algorand testnet	\$0.041 USDC, ASA 10458941	\$0.00 the facilitator sponsors it	unchanged 3.9990 before and after

Anyone can check it

```
curl testnet-idx.algonode.cloud/v2/transactions/KD6GTL...
```

```
type      axfer
sender    SMT5SJCV322C... the agent
receiver  W7TYQROP7L60... the seller
amount    2000 micro of ASA 10458941
fee       0 the buyer pays nothing
note      x402-payment-v2-1786944043684
```

That is the public Algorand indexer: not our database, and not an explorer we picked.

Why the buyer pays no fee

The payment ships as an atomic group of two. Either both execute or neither does.

[0] Facilitator's fee transaction fee 2000

[1] **Buyer's USDC transfer** fee 0

So an agent needs one asset, not two. It never has to go and acquire a native token before it can spend a dollar.

The chain choice is a product decision.

WHAT A MICRO-PAYMENT MARKET NEEDS	WHAT ALGORAND GIVES	WHY A USER FEELS IT
Prices that are actually prices	USDC as a native asset, 6 decimals	\$0.005 is 5000 units, exactly. No oracle, no conversion table, no drift between the quote and the charge.
Buyers who hold one thing	Fee sponsorship inside an atomic group	An agent funds a USDC balance and nothing else. Onboarding drops from two assets to one.
Fees that do not eat the sale	A flat fee near zero, paid by the facilitator	A \$0.002 call is viable. Where fees are variable and high, it simply is not.
Settlement inside a request	Instant finality, seconds not minutes	Payment fits inside the HTTP round trip, so an agent is never left holding a pending call.
Someone else to run the plumbing	GoPlausible's hosted facilitator	No key, no signup, and no infrastructure of ours in the settlement path. One less thing to trust and to operate.

The previous version of this project settled on another chain, and the port took a chain abstraction rather than a rewrite. **Everything above is why Algorand is now the default**, not merely the newest option.

We take a cut of what settles. Nothing settles, we earn nothing.

REVENUE MODEL

80 / 20

The publisher keeps 80% of every call. The marketplace takes 20%, and only on money that actually moved.

NO FLOOR

\$0.002 works

No minimum charge, no monthly fee and no invoice, because settlement costs the seller nothing to receive.

ALIGNED

Usage, not seats

We are paid when a listing is genuinely useful. A listing nobody calls costs us nothing and earns us nothing.

Why it compounds

- **Reputation cannot be moved.** A listing's standing comes from settled payments, so it cannot be carried to a competitor or bought.
- **Discovery is the moat.** Agents shop where the catalog is. Publishers list where the agents are.
- **Every call is a signal.** What agents actually pay for, and at what price, is demand data nobody else holds.

Where it honestly stands

- The 80/20 split is **modelled and shown in the dashboard**. On-chain, payment currently goes to a single treasury.
- Per-seller payouts are the next step, and need each seller to opt into USDC once.
- Testnet only, by design. No real money has changed hands.

We built the market. The protocol is the protocol.

Who does what

Decide the price and the payee	us
Build and emit the 402	x402ResourceServer
Build and sign the payment group	ExactAvmScheme
Verify and settle	the facilitator
Sponsor the fee	the facilitator
Catalog, discovery, reputation, receipts	us

None of the payment protocol is reimplemented. All of it is `@x402-avm`, and all four packages sit on an executed path.

Built to outlive one chain

There is a chain picker in the nav. One click re-quotes every price in a different asset, swaps the network, changes which signer moves the money, and repoints every receipt link.

```
# same URL, same product, different rails
algorand → 2000      micro USDC  ASA 10458941
casper   → 86580087  motes WCSR  CEP-18
```

SELF-TEST

9 / 9

END TO END

5 / 5

CHAINS

2

Shipped, and honest about the rest.

Working today

- A catalog of 14 paid listings, discoverable by humans and machines
- Real x402 settlement in USDC on Algorand testnet, 6 transactions on chain
- An agent that plans a task, buys four tools and respects a budget
- CLI and MCP server, both ordinary x402 clients with their own keys
- A chain picker that moves the whole product between two chains

Prototype	agentifyos.xyz
Agent demo	agentifyos.xyz/agent
Paid endpoint	/api/t/algo-market-data
Repo	github.com/0xWeb3Research/agentifyos

Next, in order

- **Wallet checkout** with Pera and Defly, so a buyer pays from their own wallet instead of a demo account
- **Per-seller payouts**, turning the 80/20 split from modelled into settled
- **Mainnet**, which is the same code path and one environment variable
- **Cross-market discovery**, so agents shop every x402 seller, not only OURS
